SciFI 4 b

Observational Feasibility

Observability

Visibility Function

Data Reduction and Analysis

Data Reduction

Data Analysis

Conclusions

- Discovered by E. Fantastico in 2006

- $m \cdot \sin i = 8 M_J$

- orbital elements:

$$a = (0.40 \pm 0.005) \text{ AU}$$

$$e = 0.0 \pm 0.01$$

$$P = (185 \pm 1) \text{ days}$$

$$\omega \sim 83^\circ$$

$$\Omega \sim 343^\circ$$

- predicted inclination (A. Imaginär et al. 2007)

$$i = 55^\circ$$

The planet is within the AMBER field of view ($\sim 46 \text{ mas}$)

SciFI 4 b

Observational Feasibility

Observability
Visibility Function

Data Reduction and Analysis

Data Reduction
Data Analysis

Conclusions

- errorbars are to large for ASPRO modeling (at least in the planet case), **BUT**
- using the properties and orbital parameters of the planet from RadVel measurements reduces the parameter space and the possible models
- combination with other observing techniques, e.g. 'doppler imaging' possible

Visibility Function

Data Reduction and Analysis

Data Reduction
Data Analysis

Conclusions

- with current performance of AMBER it is hardly possible to confirm RadVel planet candidates, even for young and nearby systems
- only with largest baselines on UTs
- range of possible orbital constellations (separation, flux ratio ...) is very small
- Orbital phase of companion should be known
- Models has to be constrained by other observations, e.g. radial velocity measurements
- the things are getting better in the brown dwarf regime
- detection of extrasolar planets remains a challenge
